Local Cluster Substructure Survey

(P.I. Graham Smith)

<http://www.sr.bham.ac.uk/locuss/>

AIM: To understand the impact of recent hierarchical infall history of clusters on their baryonic content – galaxies and hot intracluster gas.

- Observable cluster scaling relations show intrinsic scatter from cluster to cluster. How does this scatter relate to their recent assembly history?
- Transformation of infalling galaxies through different environments:
field / filaments / groups / cluster cores.

LoCuSS: Herschel Key Programme

A legacy survey of clusters at $z=0.2$

Summary of ISO/Spitzer results:

~10 clusters, heterogenous selection: depths, FoV

order of magnitude variations in IR populations of galaxies.

connection between cluster-cluster mergers and starburst galaxies? (Geach+ 2006; Haines + 2009; Bekki 2001)

Need: a large wide field homogenous survey of clusters

Geach+2006

LoCuSS: *Herschel* Key Programme

A legacy survey of clusters at $z=0.2$

Morphologically unbiased sample:

- $0.15 < z < 0.3$, $-70 < \text{dec} < +70 \text{deg}$, $n_{\text{H}} < 7\text{E}-20 \text{cm}^{-2}$
- ROSAT All Sky Survey catalogs: BCS, eBCS, REFLEX
- 165 clusters with $L_x > 2\text{E}44 \text{erg/s}$

Huge multi-wavelength effort (30-50% complete):

- Subaru, HST, Keck, VLT, Gemini, Chandra, XMM, SZA, Palomar, Spitzer (24 μm), GALEX, Herschel, MMT/Hectospec, KPNO, CTIO, UKIRT

LoCuSS: Herschel Key Programme

A legacy survey of clusters at $z=0.2$

Relative importance of different environmental processes:

galaxy-galaxy mergers
 $2 < \rho_{3D} < 10 \text{Mpc}^{-3}$

harassment $\sim \rho_{\text{gal}} r^2$

ram pressure stripping:

to strip the MW (Gunn&Gott 1972)

Smith+2010

LoCuSS: Herschel Key Programme

Relative importance of different environmental processes:

galaxy-galaxy mergers
 $2 < \rho_{3D} < 10 \text{Mpc}^{-3}$

harassment $\sim \rho_{\text{gal}} r^2$

ram pressure stripping:

to strip the MW (Gunn&Gott 1972)

$$\Delta(z=0.25) = 120$$
$$r_{200} = 0.75 r_{\text{vir}}$$

Smith+2010

LoCuSS: Herschel Key Programme

Strategy

- Large sample of clusters at “low” redshift ■ 100/160um observations probe SED peak ■ Probe out to $\geq 1.5r_{\text{virial}}$
- A bit more detail:
 - Global SFR (gas supply) is $\sim 2\text{-}3\times$ lower at $z\sim 0.2\text{-}0.3$ than at $z\sim 1$, but it is not negligible!
 - Observations at $z=0.2$ are $5\times$ cheaper than at $z=0.8$!
 - Optical Butcher Oemler effect shows significant cluster-cluster variations at $z\sim 0.2$
- Currently a large statistical sample is only feasible at $z\sim 0.2$
- 32 clusters \rightarrow $\sim 600\text{-}1000$ galaxies with $L_{\text{IR}} > 5 \times 10^{10} L_{\odot}$

Observations

- PACS 100um and 160um • 25x25arcmin maps • 110 sec on-sky per pixel
- Total 4.8 hours per cluster ■

Status (as of May 2010)

10 clusters observed, 8 analyzed in survey letter (Smith+ 2010, A&A Special Issue)

Conclusions:

- FIR colors of cluster galaxies at $z=0.2$ differ from local galaxy colors, as captured by CE01 and R09 SED templates -- an environmental effect?
- no correlation between cluster dynamical state and total infrared luminosity
- radial profiles peak at $\sim r_{\text{vir}}$ for the cool core clusters, indicating merging may be main driver of induced star formation in clusters
- L_{IR} is generally anisotropic: the brightest infrared regions in A1835 and A1689 appear to be associated with filaments which are currently feeding the clusters.
