

Wrap-up: The Solar System and its Evolution

Paul Hartogh

Max Planck Institute for Solar System Research (hartogh@mps.mpg.de)

TNO Fundamental Properties: Size & Albedos

Müller et al. 2010, Lellouch et al. 2010, Lim et al. 2010

Mommert et al. 2012, Vilenius et al. 2012, Santos-Sanz et al. 2012

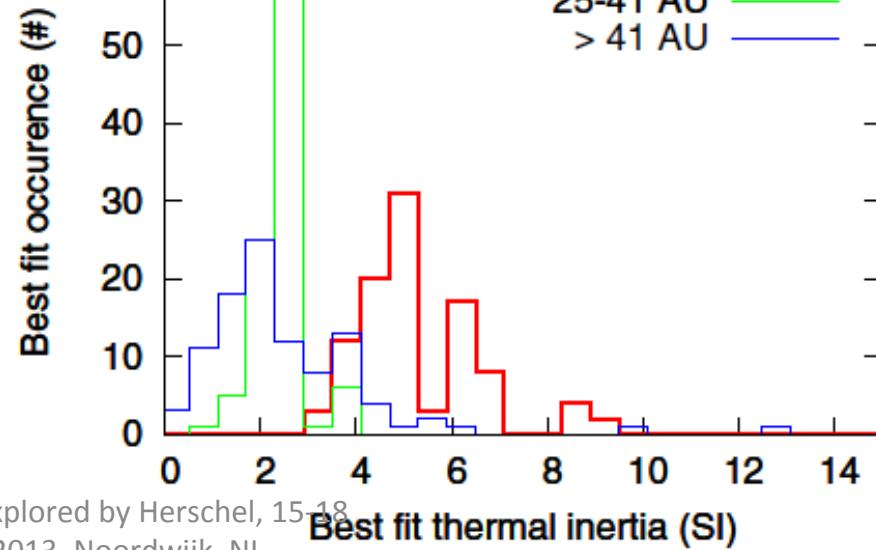

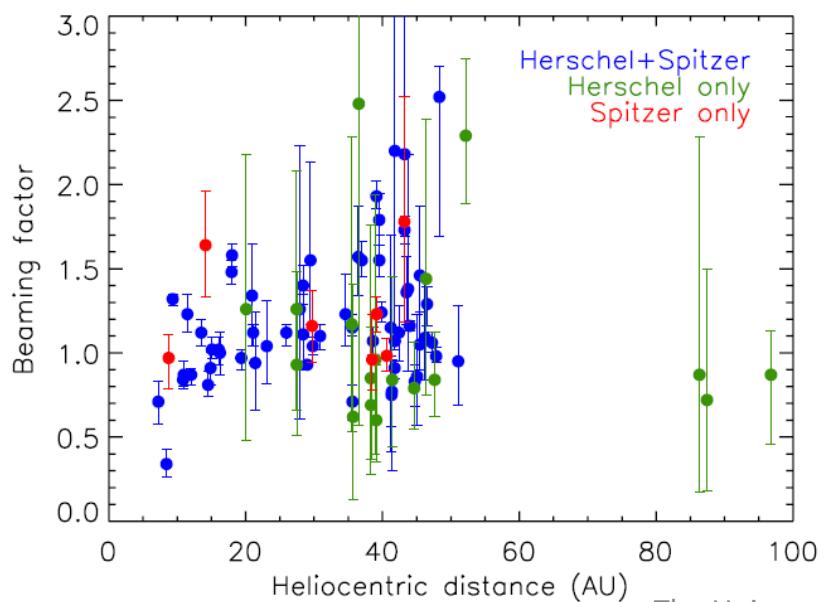

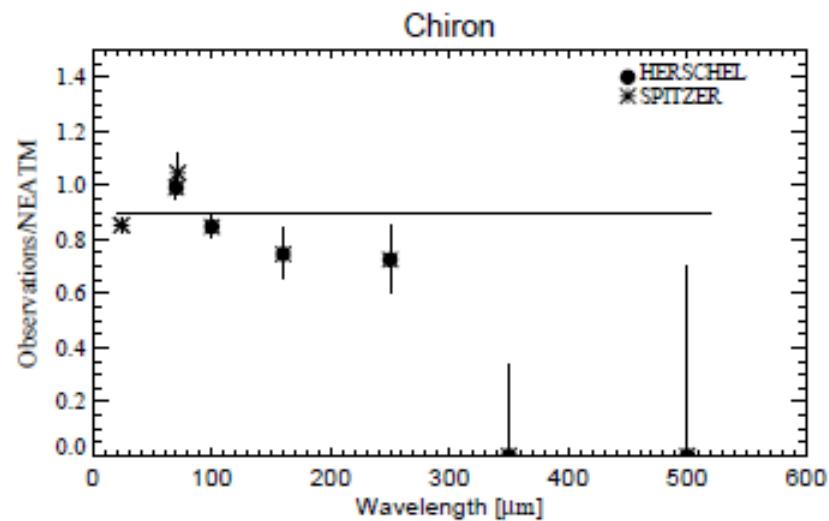

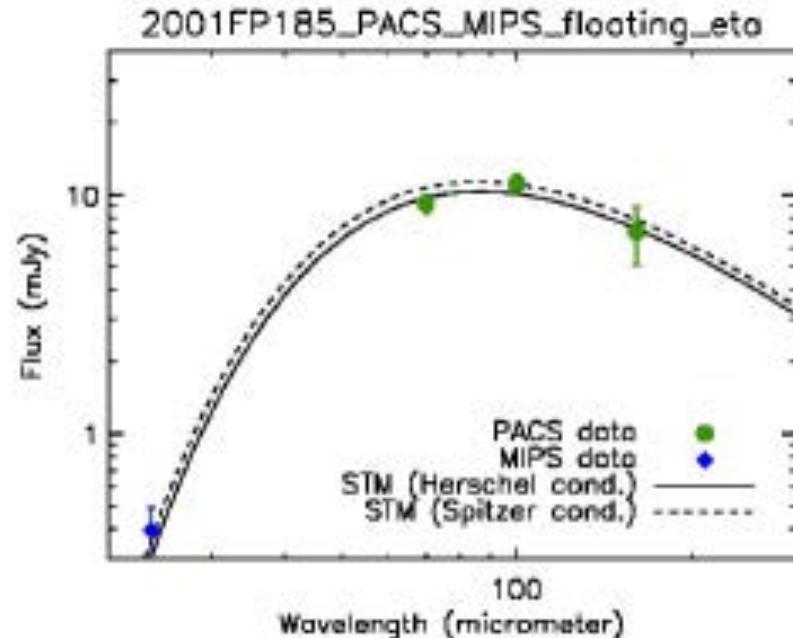

Fornasier et al. 2013, Duffard et al. 2013, Vilenius et al. 2013
 The Universe Explored by Herschel 19-18

TNOs

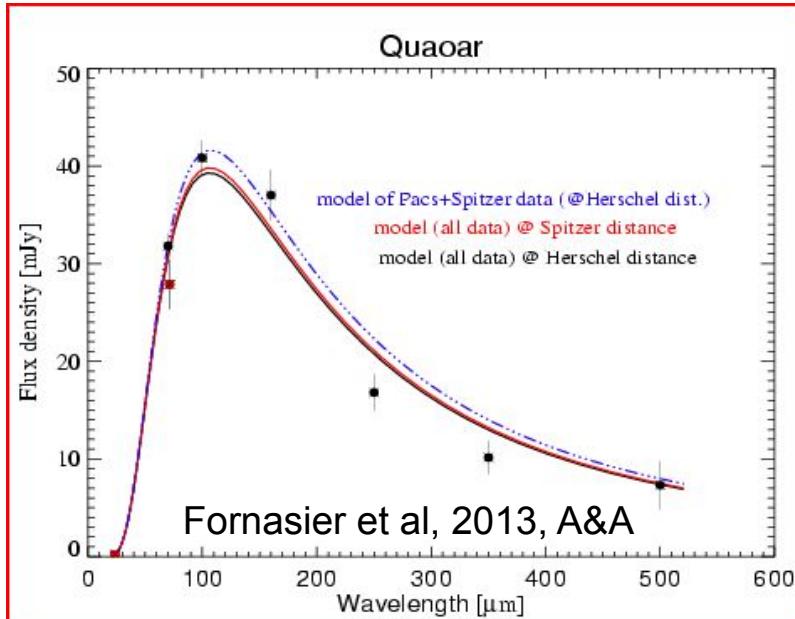

- Diameter and albedo of 115 objects with sizes from 100 to 2400 km (Pluto/Eris) and albedos from 3 to 100 %.
- Very different from the main-belt objects. Very large diversity. Object properties point to different evolution processes for different dynamic classes.
- Very high albedos require resurfacing process to maintain such a high albedo over longer timescales. Cryovolcanism for the large and high albedo objects?

TNOs

- Densities for about 25 binary systems: $0.4 \dots 2.5 \text{ g/cm}^3$: different formation mechanism?
- Thermal lightcurves (for 5 objects) show rotationally deformed bodies.
- Thermal properties point towards very rough, porous, extremely low thermal conductivity surfaces.
- TNOs have very low thermal inertia:
 - Mean value = $2.5 \text{ Jm}^{-2}\text{s}^{-1/2} \text{ K}^{-1}$
 - Decreases with increasing heliocentric distance
- Spectral emissivity of TNOs decreases with increasing wavelength

Classical TNO: 5000 Quaoar

Previous size estimates: Hubble direct: 1260 ± 190 km (Brown & Trujillo 2004); 870 ± 70 km (Frazer & Brown 2010) Spitzer radiometric: 844 ± 207 km (Stansberry et al. 2008) Spitzer radiometric: 908 ± 118 km (Brucker et al. 2009)

New occultation effective size estimate: 1111 ± 5 km (Braga-Ribas et al. 2013)

Quaoar is a binary system of known mass $(1.6 \pm 0.3) \times 10^{21}$ kg with a smaller companion, Weywot.

With the size determined from Herschel data we derive a **density of 2.2 ± 0.5 g/cm³**, similar to that of Pluto (Frazer & Brown (2010) got an unlikely density of 4.2 ± 1.3 g/cm³, from their HST Quaoar size estimation). Assuming the same albedo for the 2 bodies, we derive a diameter of 1070 ± 38 km for Quaoar, and 81 ± 11 km for Weywot.

NEATM RESULTS:

$$p_v (\%) = 12.7 \pm 1.0$$

$$D = 1074 \pm 38 \text{ km}$$

$$\eta = 1.73 \pm 0.08$$

$\eta_{\text{mean}} = 1.47 \pm 0.43$ (19古典天体, from Vilenius et al 2012)

Ammonia in comets with HIFI

Observed spectra:

Hartogh et al. Nature (2011)

S/N = 10

The Universe Explored by Herschel, 15-18
October 2013, Noordwijk, NL

S/N = 60

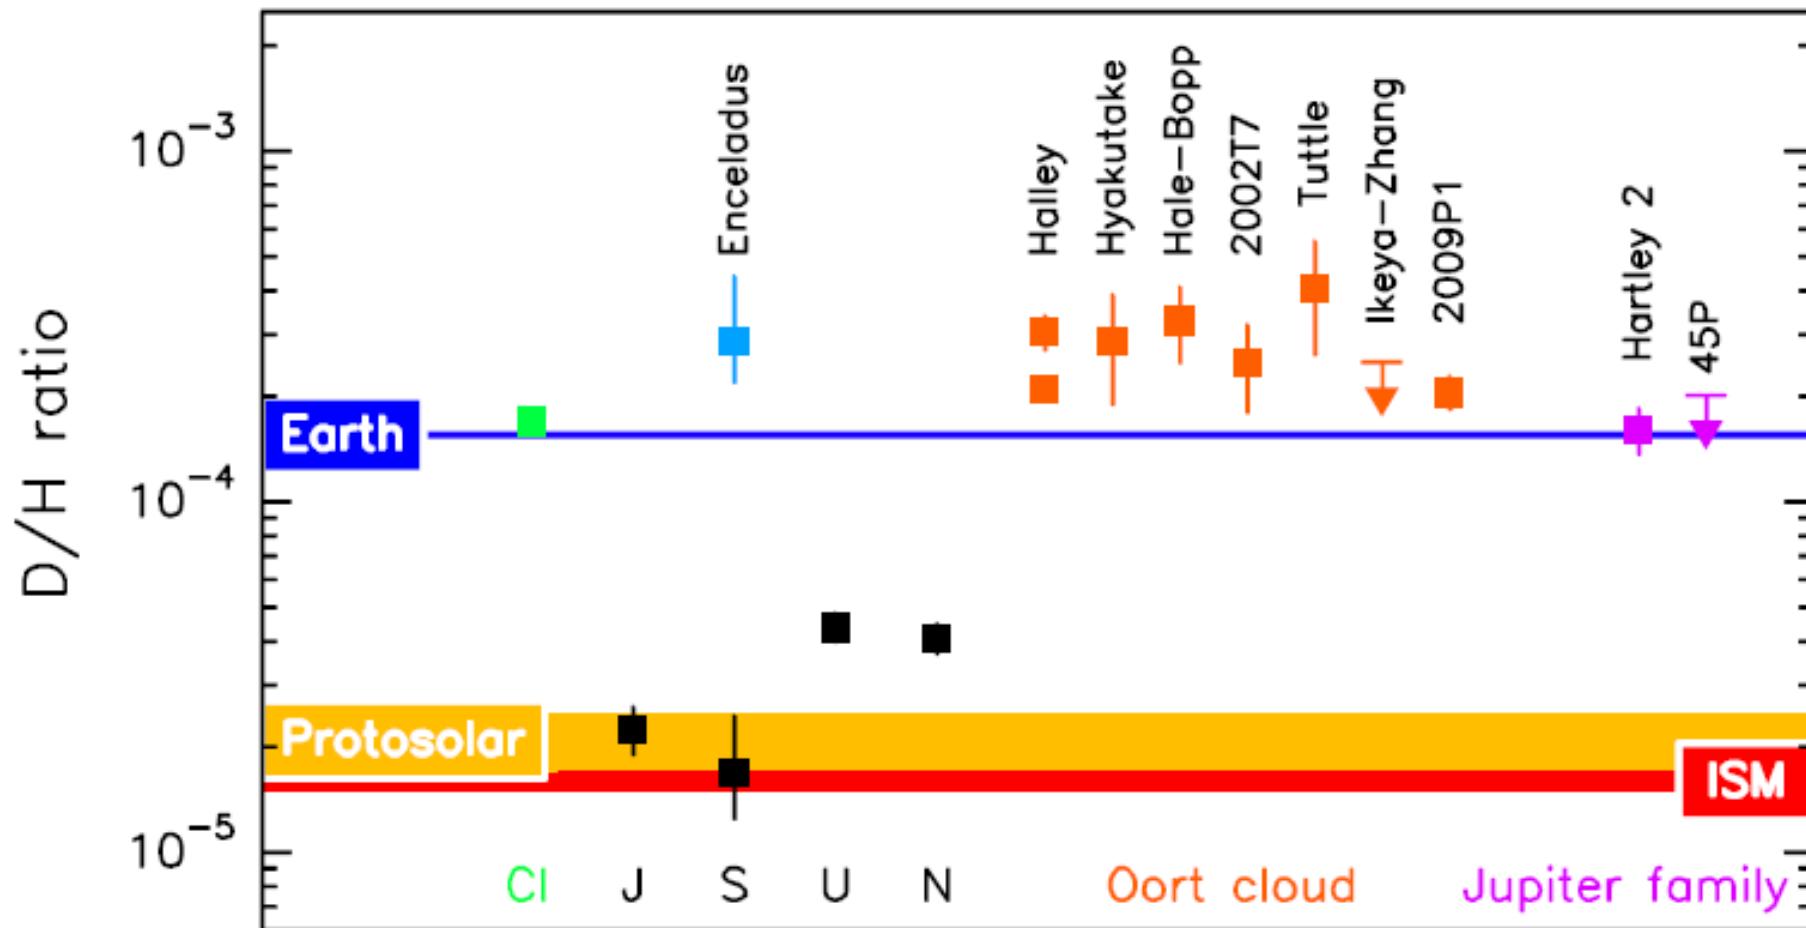

Analysis of the observations

- **Excitation model** : collisions with H₂O, electrons and infrared pumping, gas temperature determined by other observation (e.g. methanol lines at IRAM/CSO/SMT)
- → the HDO/H₂¹⁸O production rate ratio is not very sensitive to the model parameters (similar transition: J = 1₁₀-1₀₁)
- **Hypothesis** : $^{16}\text{O}/^{18}\text{O} = 500 \text{ (+/- 10\%)} \text{ (VSMOW)}$
 $(520 \pm 30 \text{ in 4 comets with Odin})$

$$\Rightarrow D/\text{H} = (1.61 \pm 0.24) \times 10^{-4}$$

$$D/\text{H(VSMOW)} = 1.558 \pm 0.001 \times 10^{-4}$$

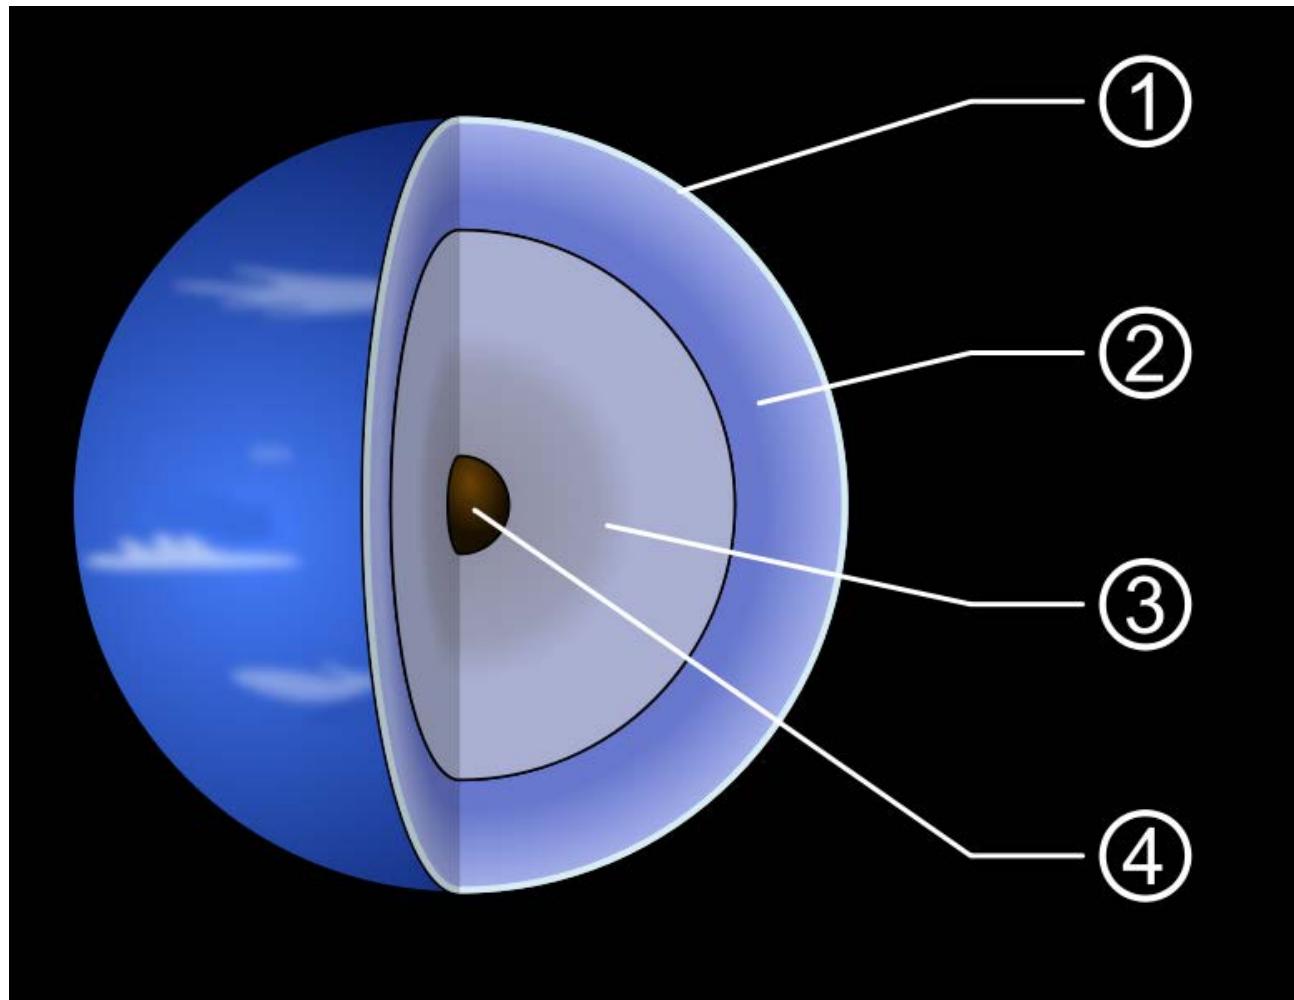

Deuterium in Solar System after Herschel

D/H in Uranus and Neptune

- D/H in Jupiter and Saturn protosolar, i.e. main component is hydrogen
- D/H Uranus and Neptune substantially higher => equilibrated water/hydrogen and possibly organic molecules (highly D-enriched in interstellar medium): “Ice giants”
- D/H in hydrogen may be used to constrain the D-enrichment of ices or the amount of ices for a given D/H.

The internal structure of the ice giants

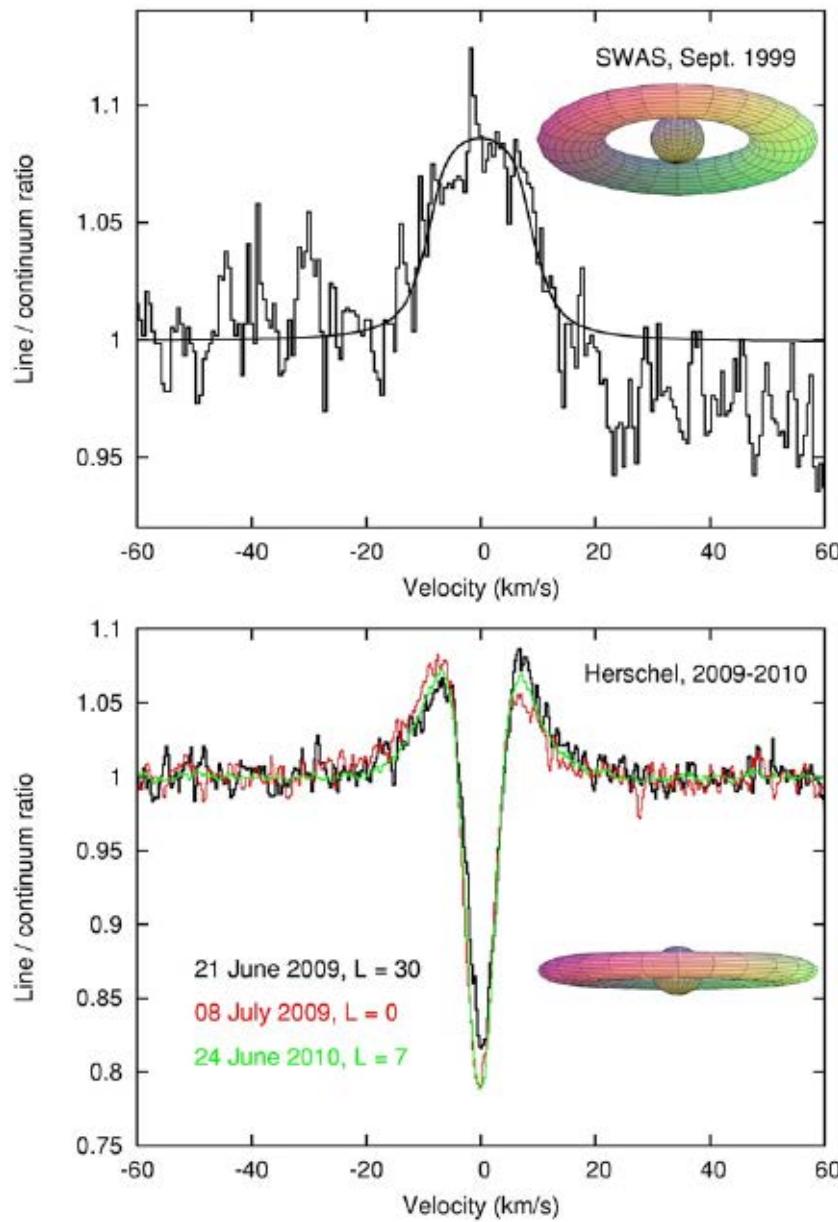

1. Upper atmosphere, top clouds
2. Atmosphere consisting of hydrogen, helium and methane gas
3. Mantle consisting of water, ammonia and methane ices
4. Core consisting of rock (silicates and nickel-iron)

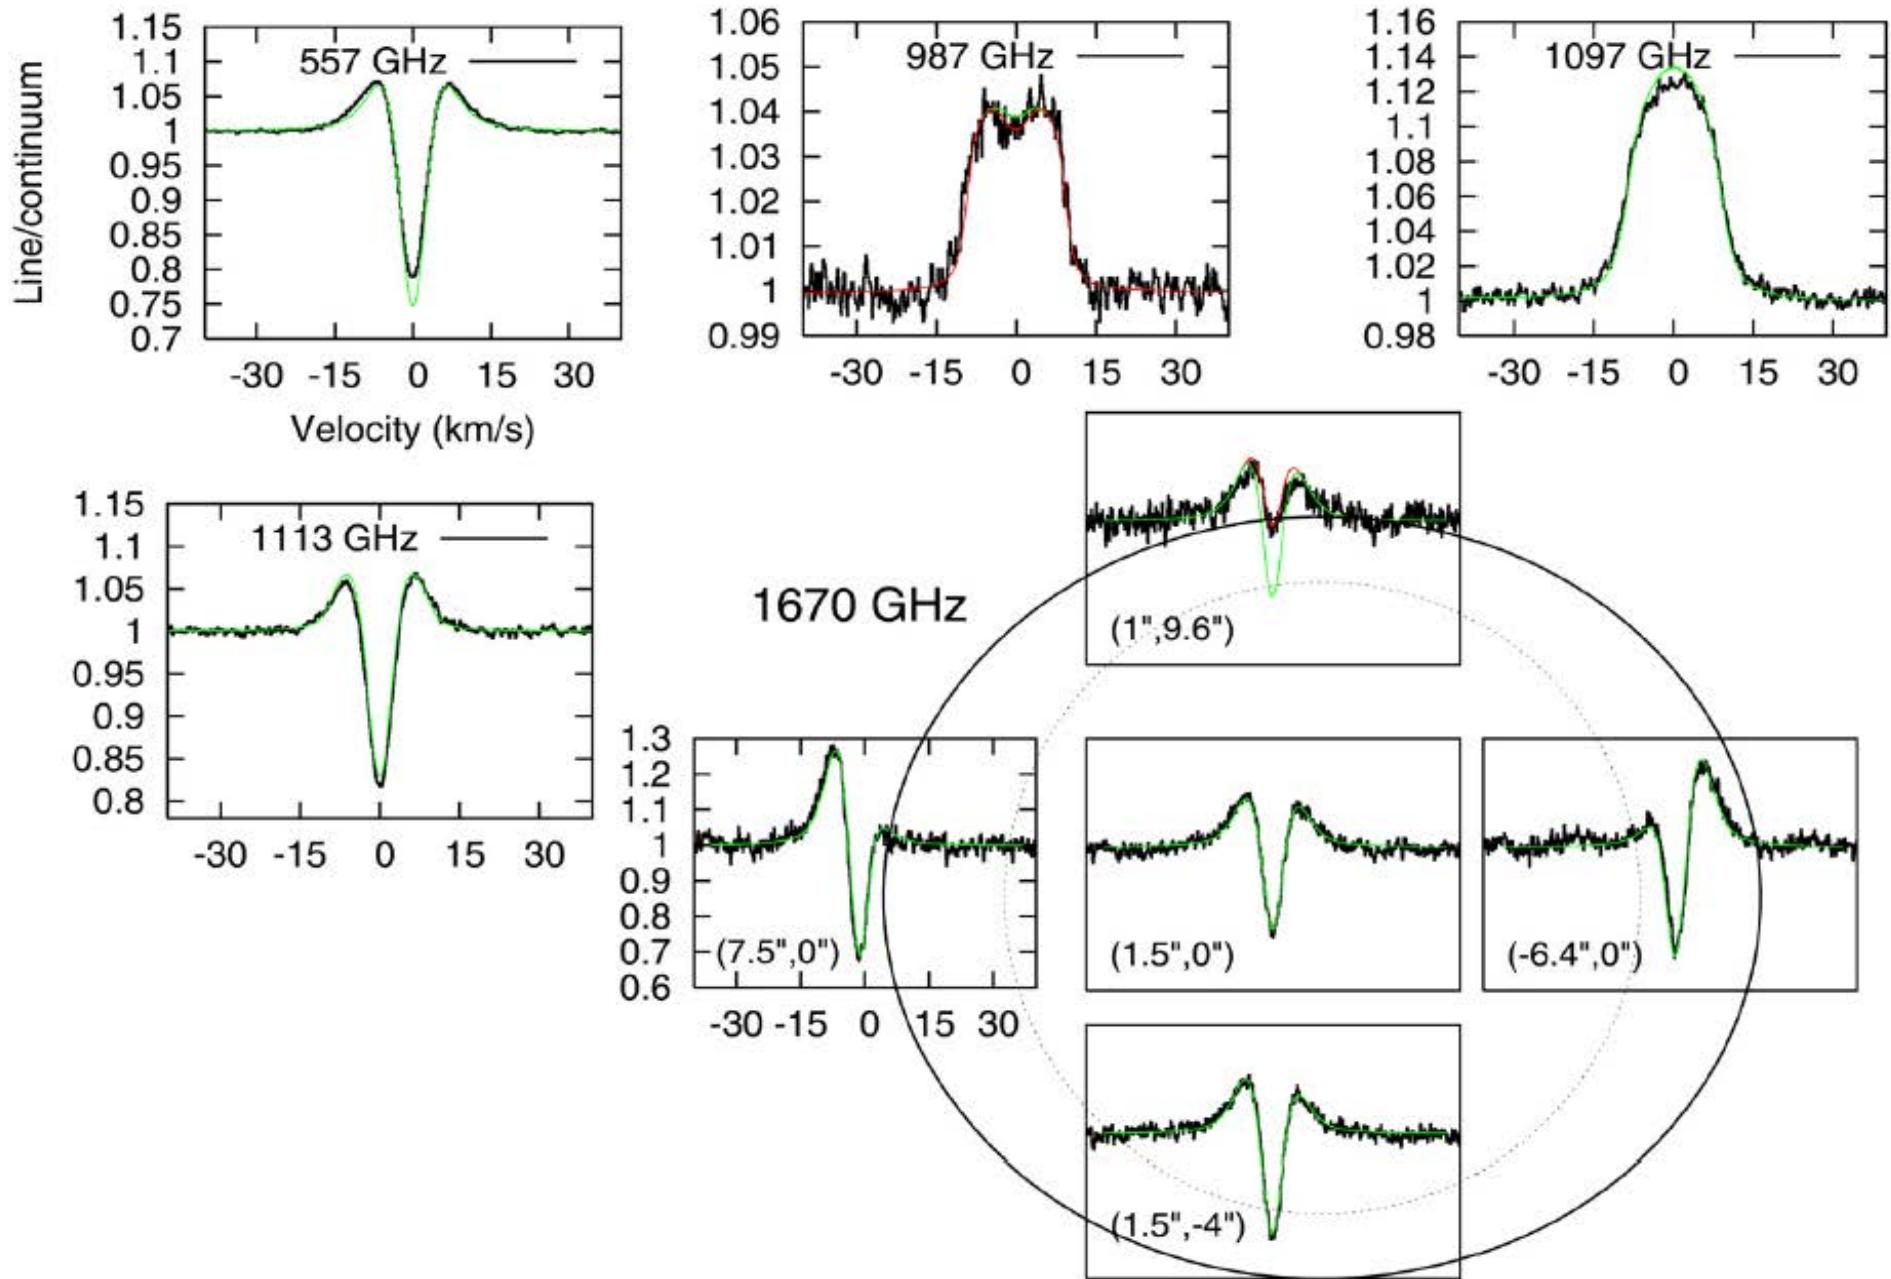

Ice Giants may be Rock Giants

- PACS values show the same D/H for both planets
- PACS values smaller than ISO values:
 - Neptune: 41 ± 4 ppm (65 ppm)
 - Uranus: 44 ± 4 ppm (55 ppm)
- Formation models (e.g. Podolak, 1995) predict 70-100 % ice and a rather small amounts of rocky (SiO_2) material. Based on these models the very low (64 ppm) D/H of ices are derived.
- Assuming cometary (150-300 ppm) isotopic ratios we get an ice mass fraction of only 14-32 %, meaning that the planets are rock-dominated.

Lellouch et al, 2010, A&A; Feuchtgruber et al., A&A 2013

First detection of the Enceladus water torus

Conclusions Enceladus water torus

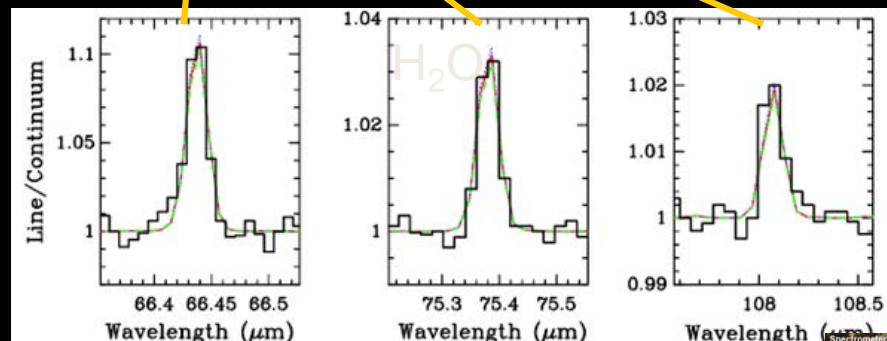

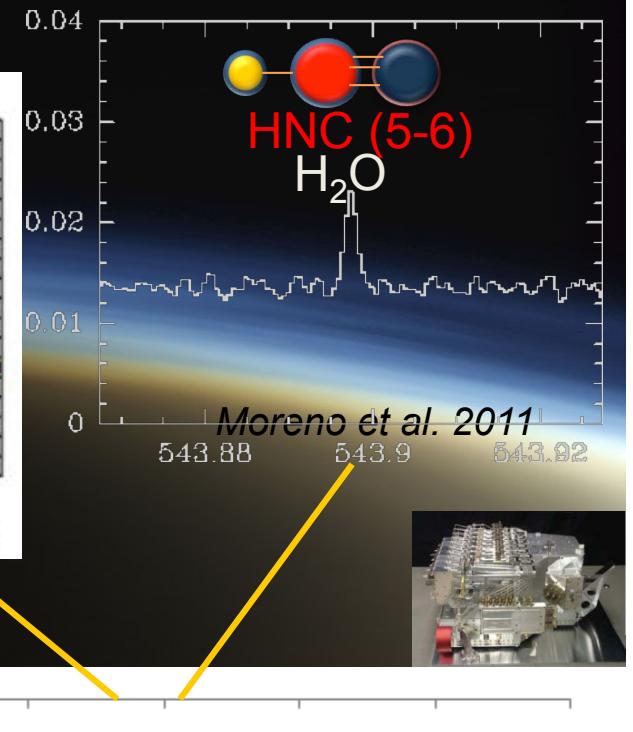

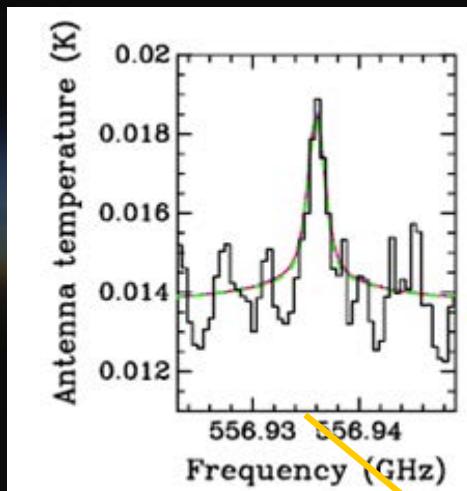

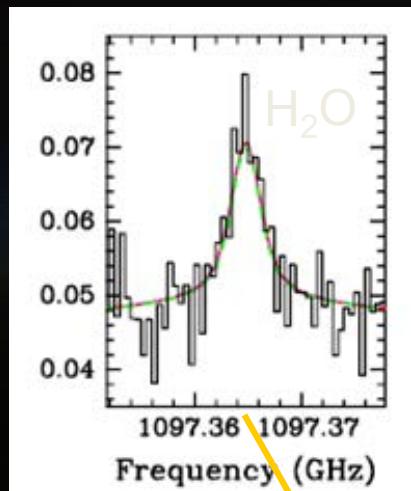

- Extension about 10 Saturn radii (R_s)
- Highest density around a distance of $4 R_s$
- Thickness about 50000 km
- About 3 % of the water produced by Enceladus rains into the upper atmosphere of Saturn
- Enceladus is rather likely the source of stratospheric water in Saturn and Titan

Photolytic fractionation of $^{14}\text{N}^{14}\text{N}$ and $^{14}\text{N}^{15}\text{N}$ (Earth = 272)

Measurement	$^{16}\text{O}/^{18}\text{O}$	Reference
JCMT	~ 250	Owen et al. 1999 (never-published)
SMA	400 ± 41	Gurwell 2008 (unpublished)
Herschel/SPIRE	380 ± 60	Courtin et al. 2012

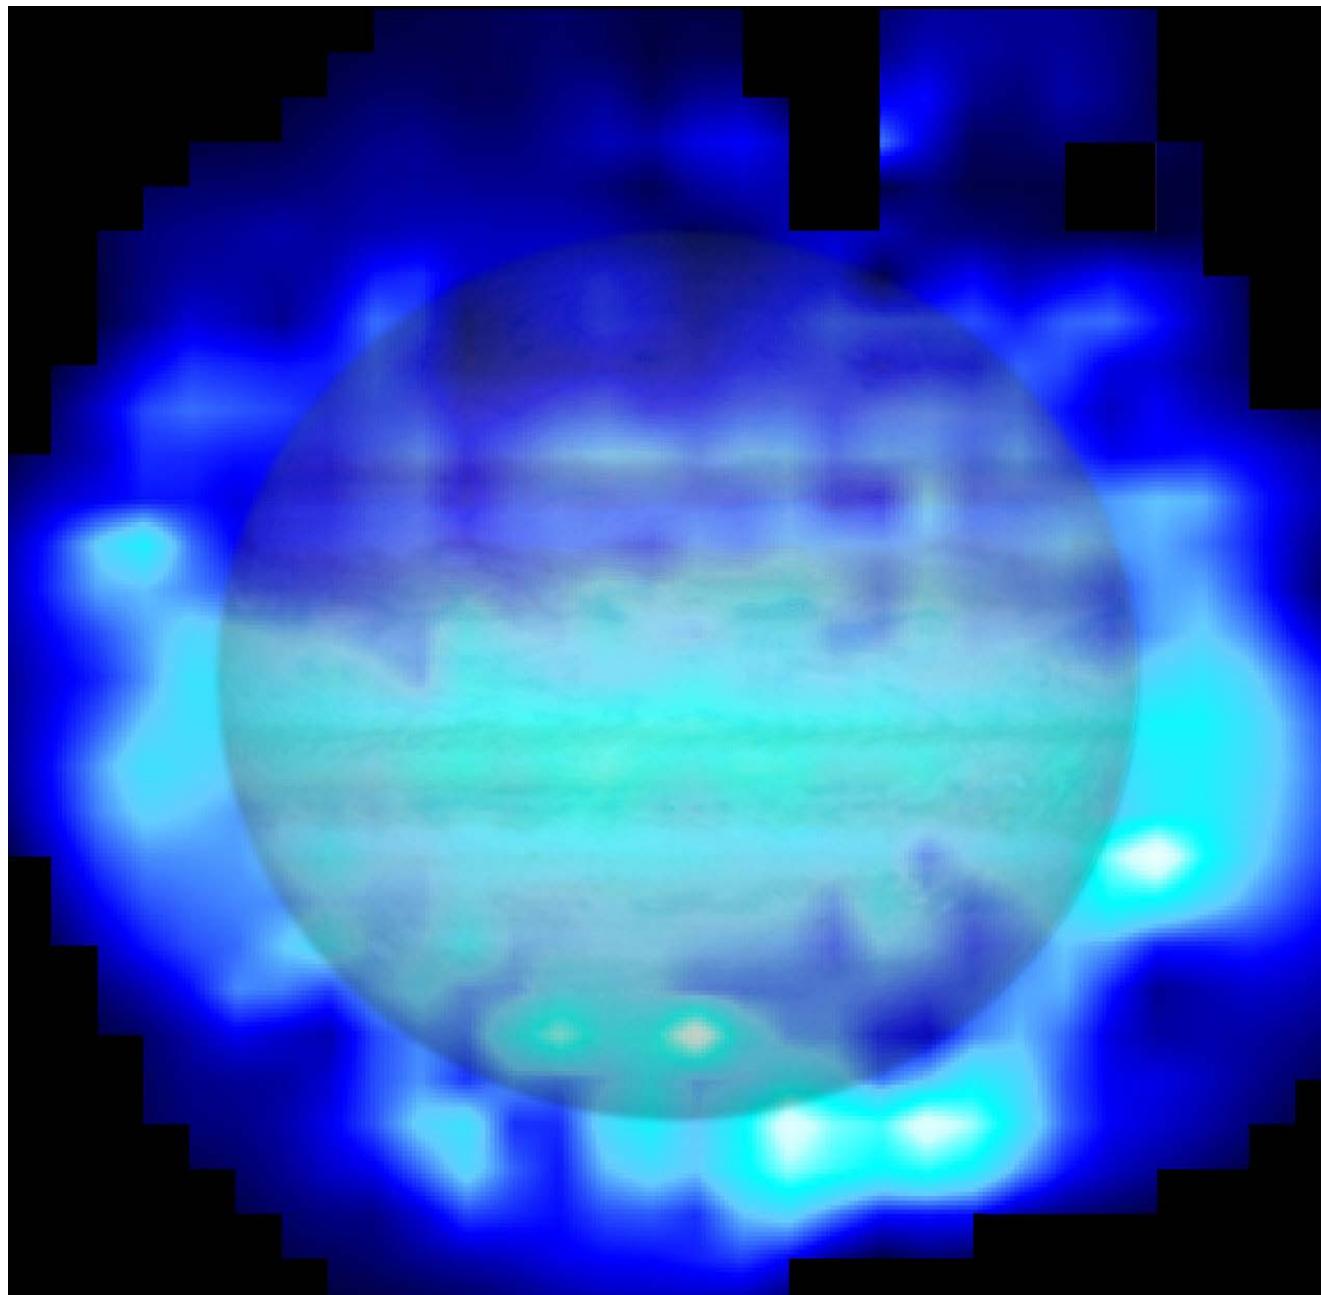

First documented measurement of Titan's $^{16}\text{O}/^{18}\text{O}$ in CO, value 24% lower than the Terrestrial ratio (Earth = 500) → $^{16}\text{O}/^{18}\text{O}$ depletion in Titan

SL9 impacts 1994 (VIS/IR) at 44 S

Credits: NASA-HST/ U. Hawaii

Water distribution observed by PACS

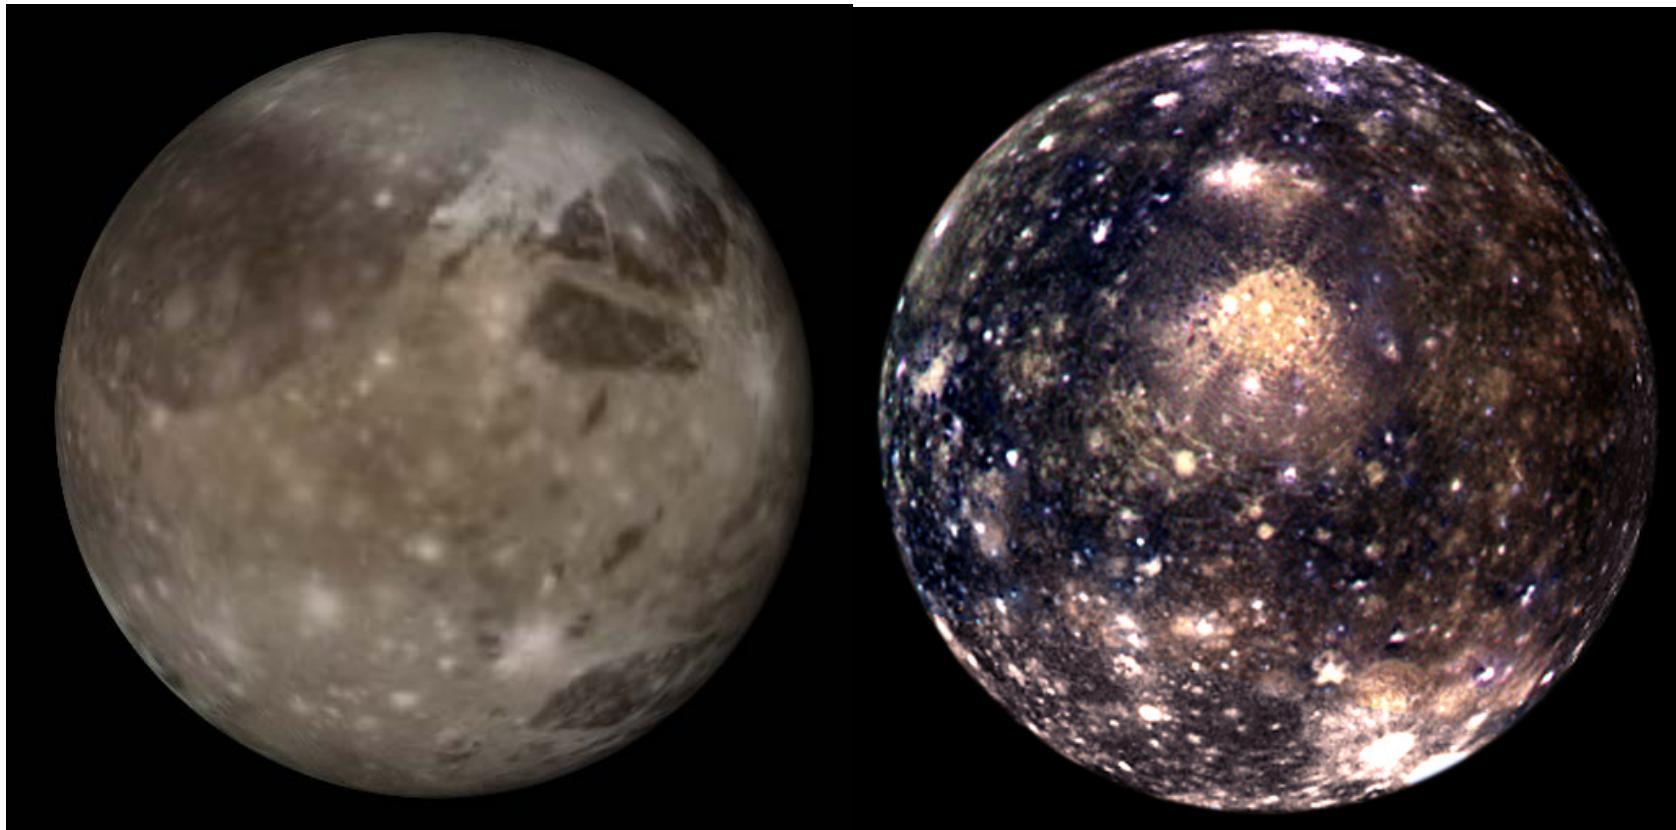

SL9 impact main source of stratospheric water in Jupiter

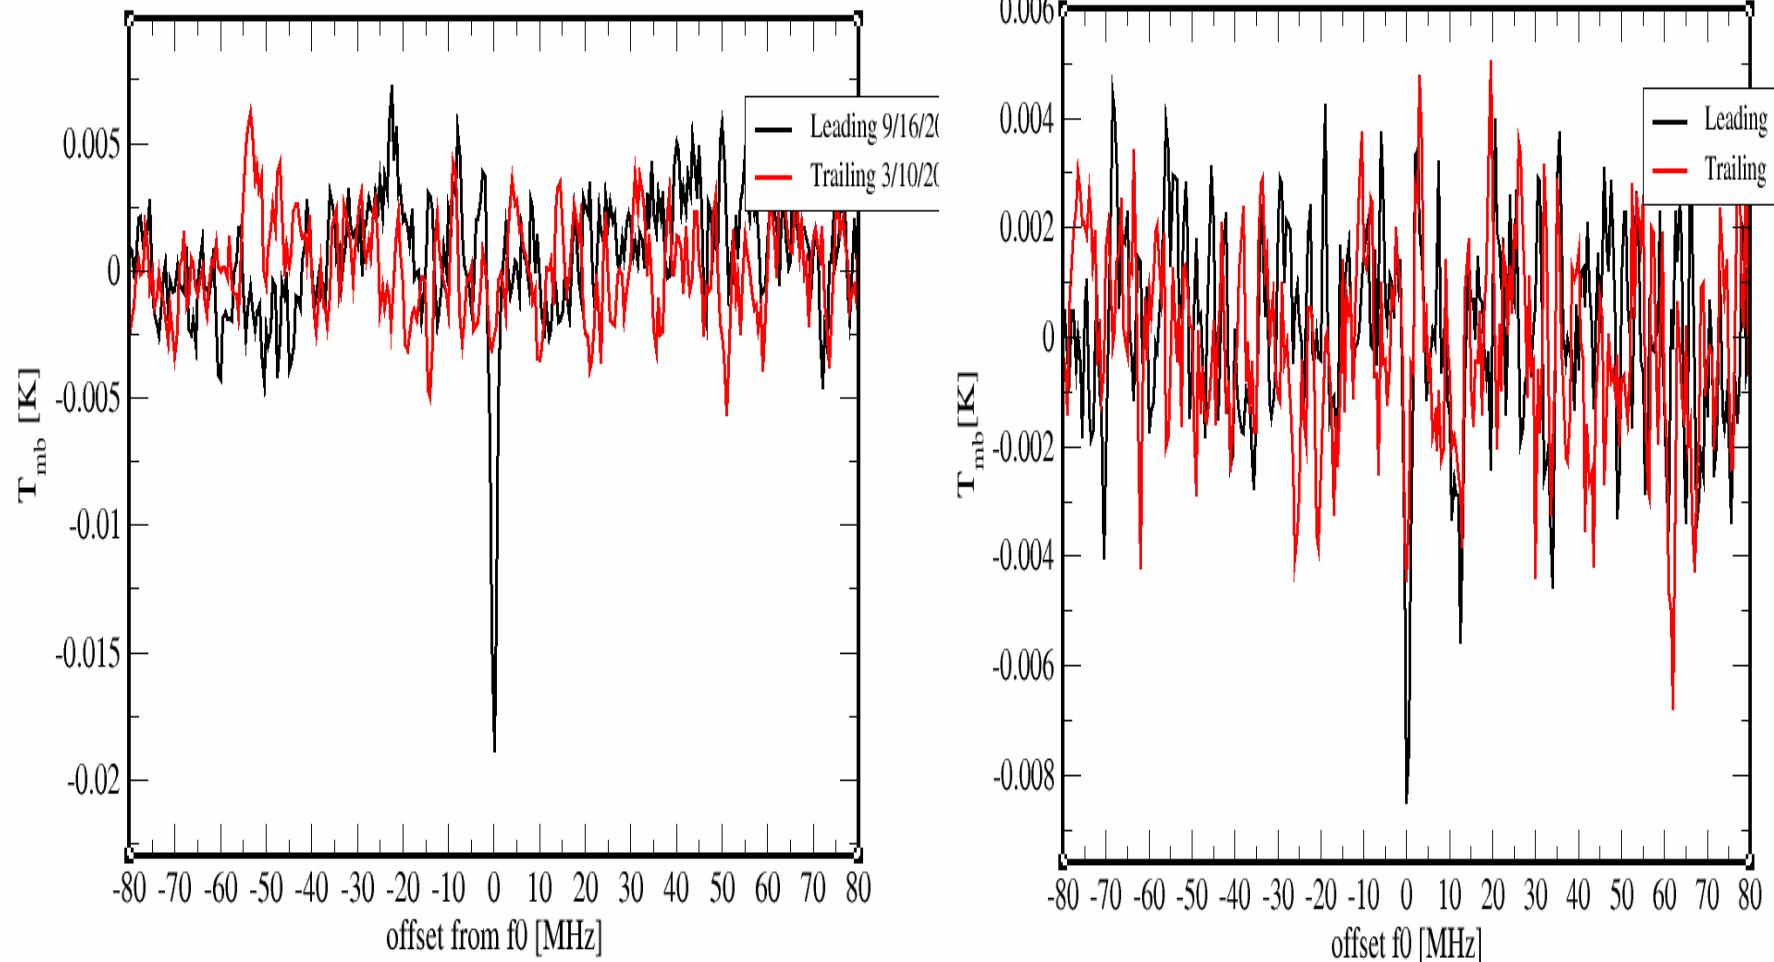

- No feature found indicating a satellite/ring source
- Vertical distribution does not fit IDP source
- Horizontal distribution of water favors SL9 impact, hemispheric asymmetry: Globally averaged column density $3 \times 10^{15} \text{ cm}^{-2}$ with 2-3 times more water in the south.

Cavalie et al., A&A 2013

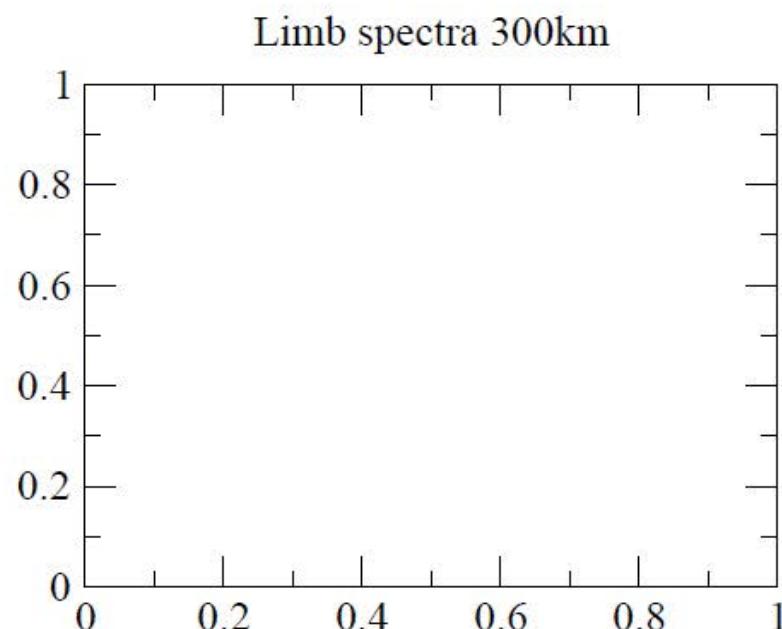

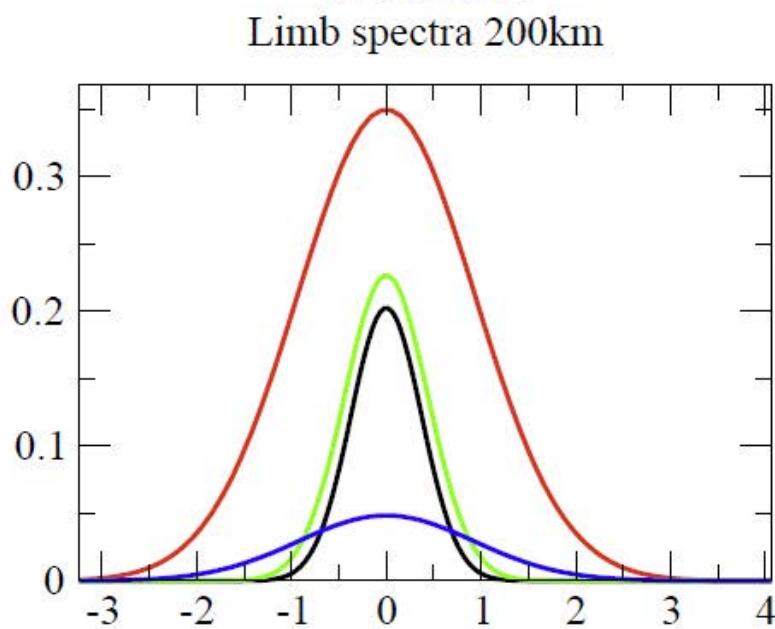

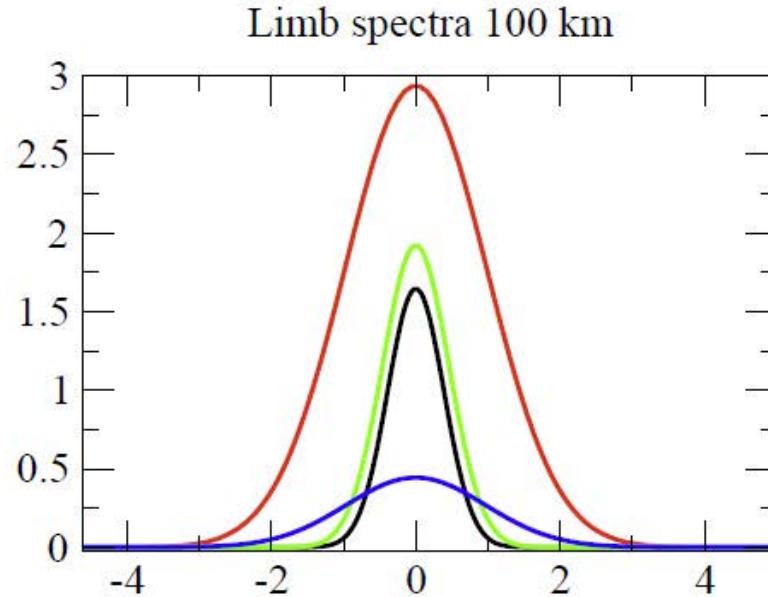

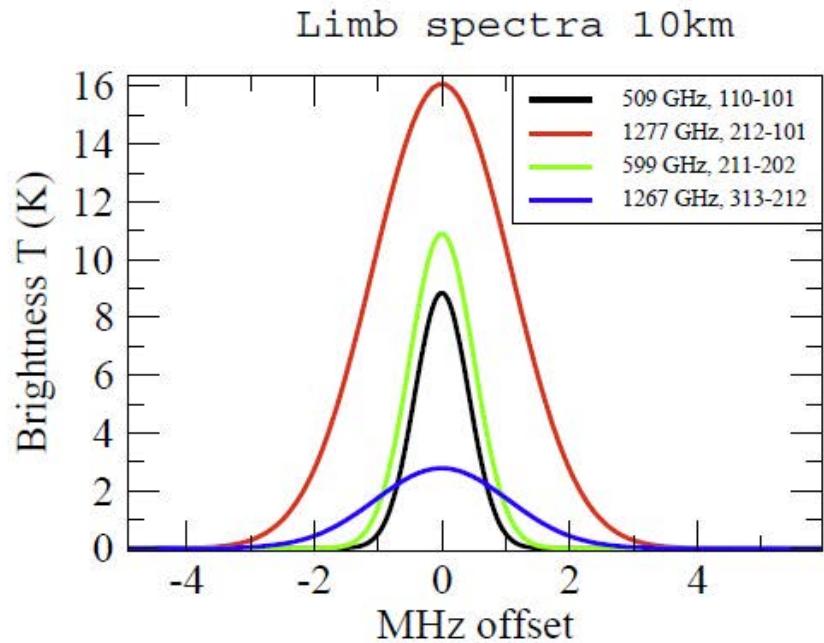

Ganymede and Callisto leading sides

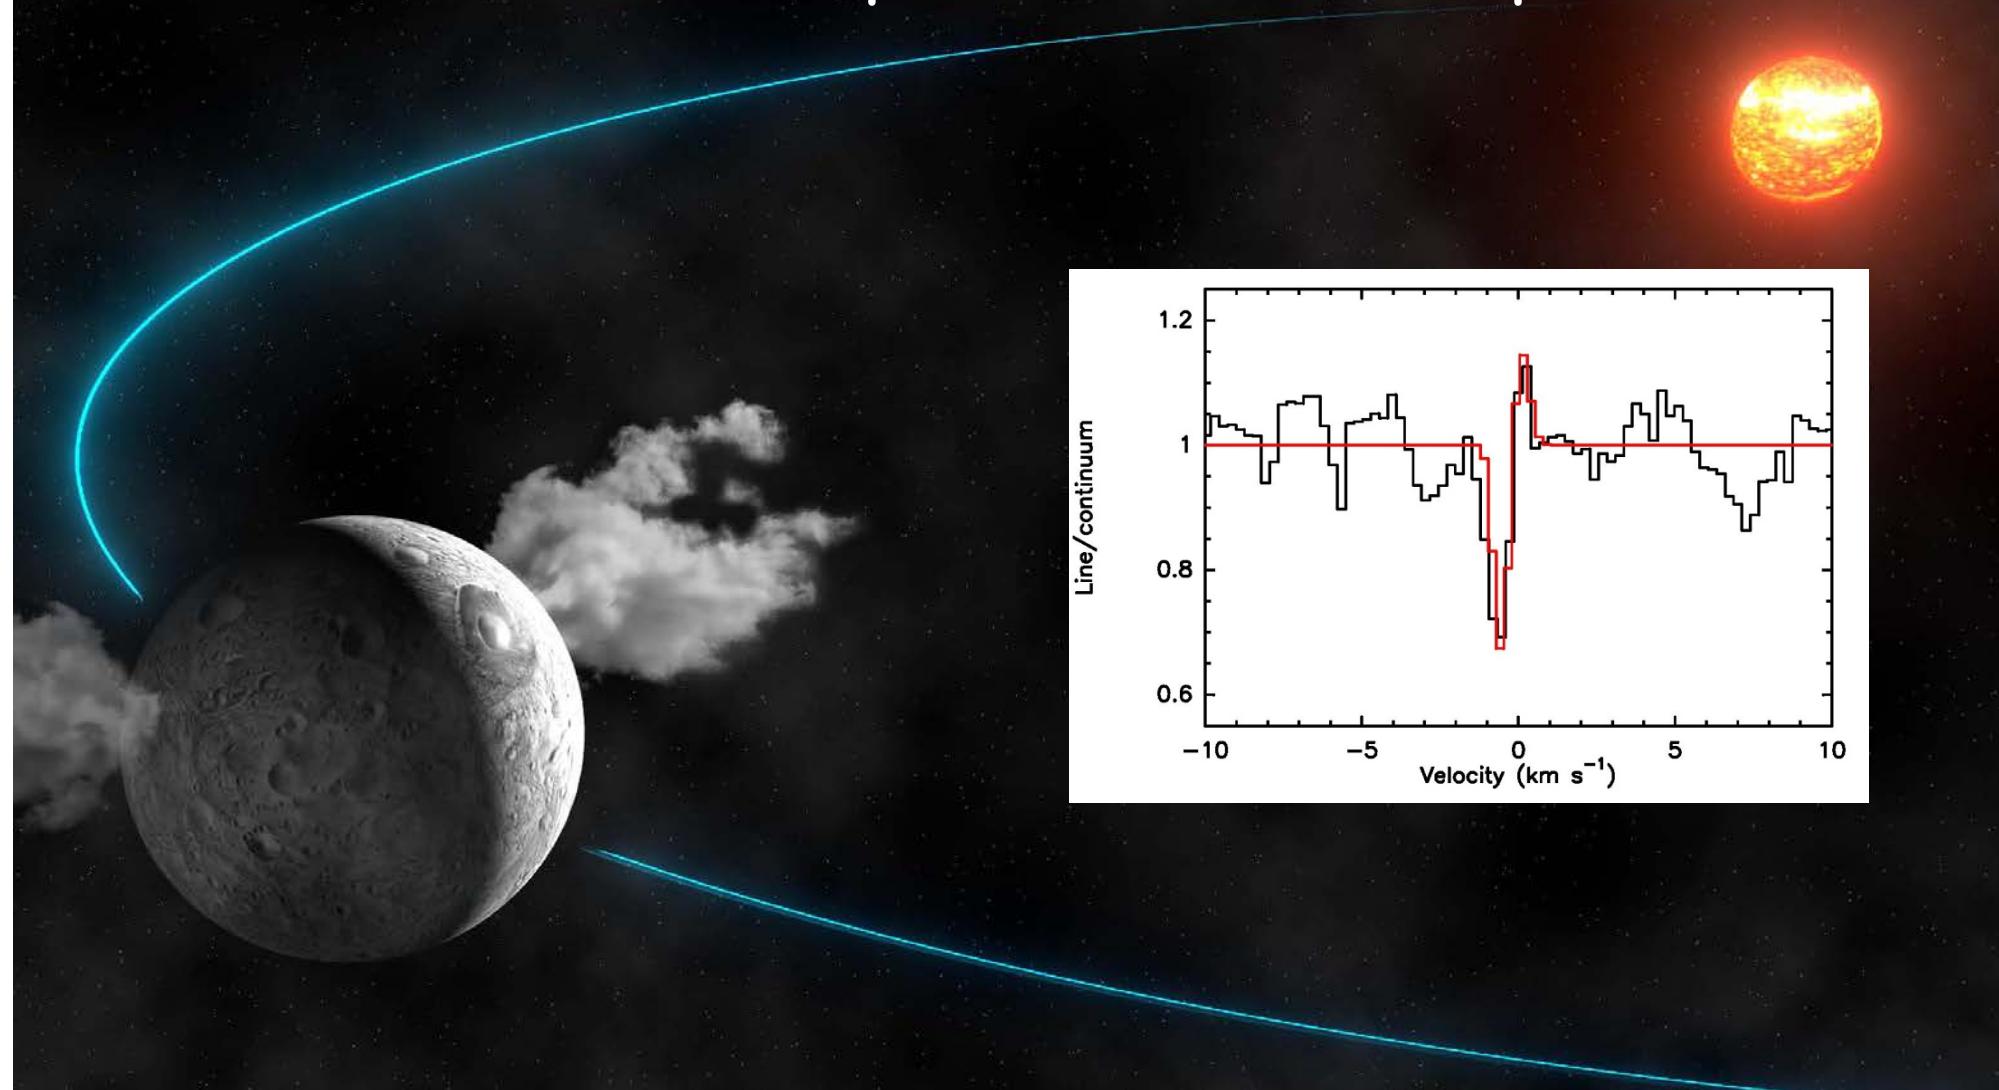

Ganymede and Callisto have leading sides water atmosphere

Received 6 August 2012; Accepted 25 August 2012

Main belt extends from about 2.5 – 3.6 AU. MBCs probably originate in the outer main belt. Comet-like (dust) tails observed. Origin of tail not clear. Tails are usually volatiles driven, however difficult to understand for main belt comets. Search for volatiles with Herschel

Upper limit of water production $< 4 \times 10^{25}$ molecules/s

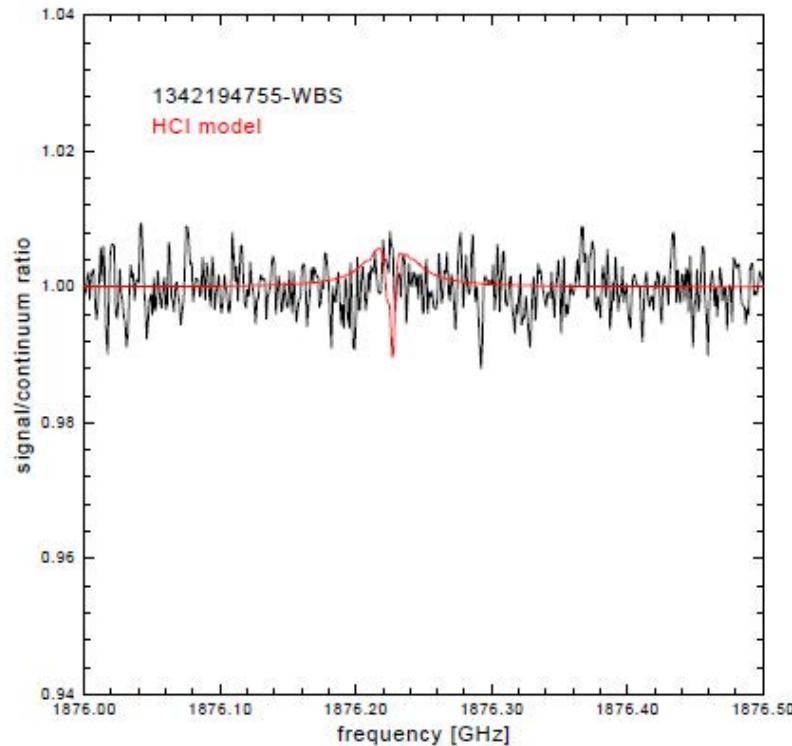

Mars: Oxygen isotopic ratios telluric

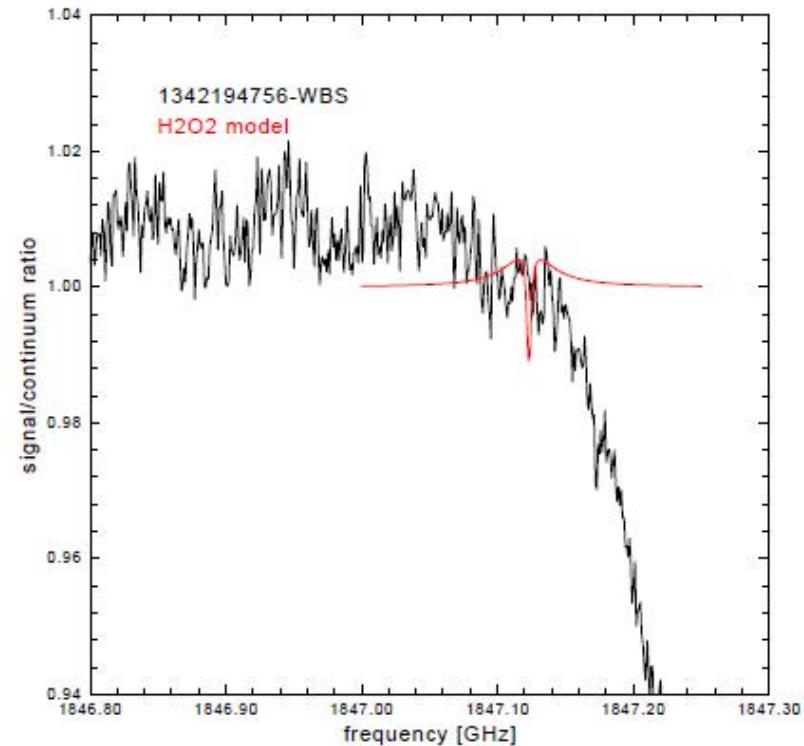

Upper limits on HCl and H₂O₂, Ls=78°

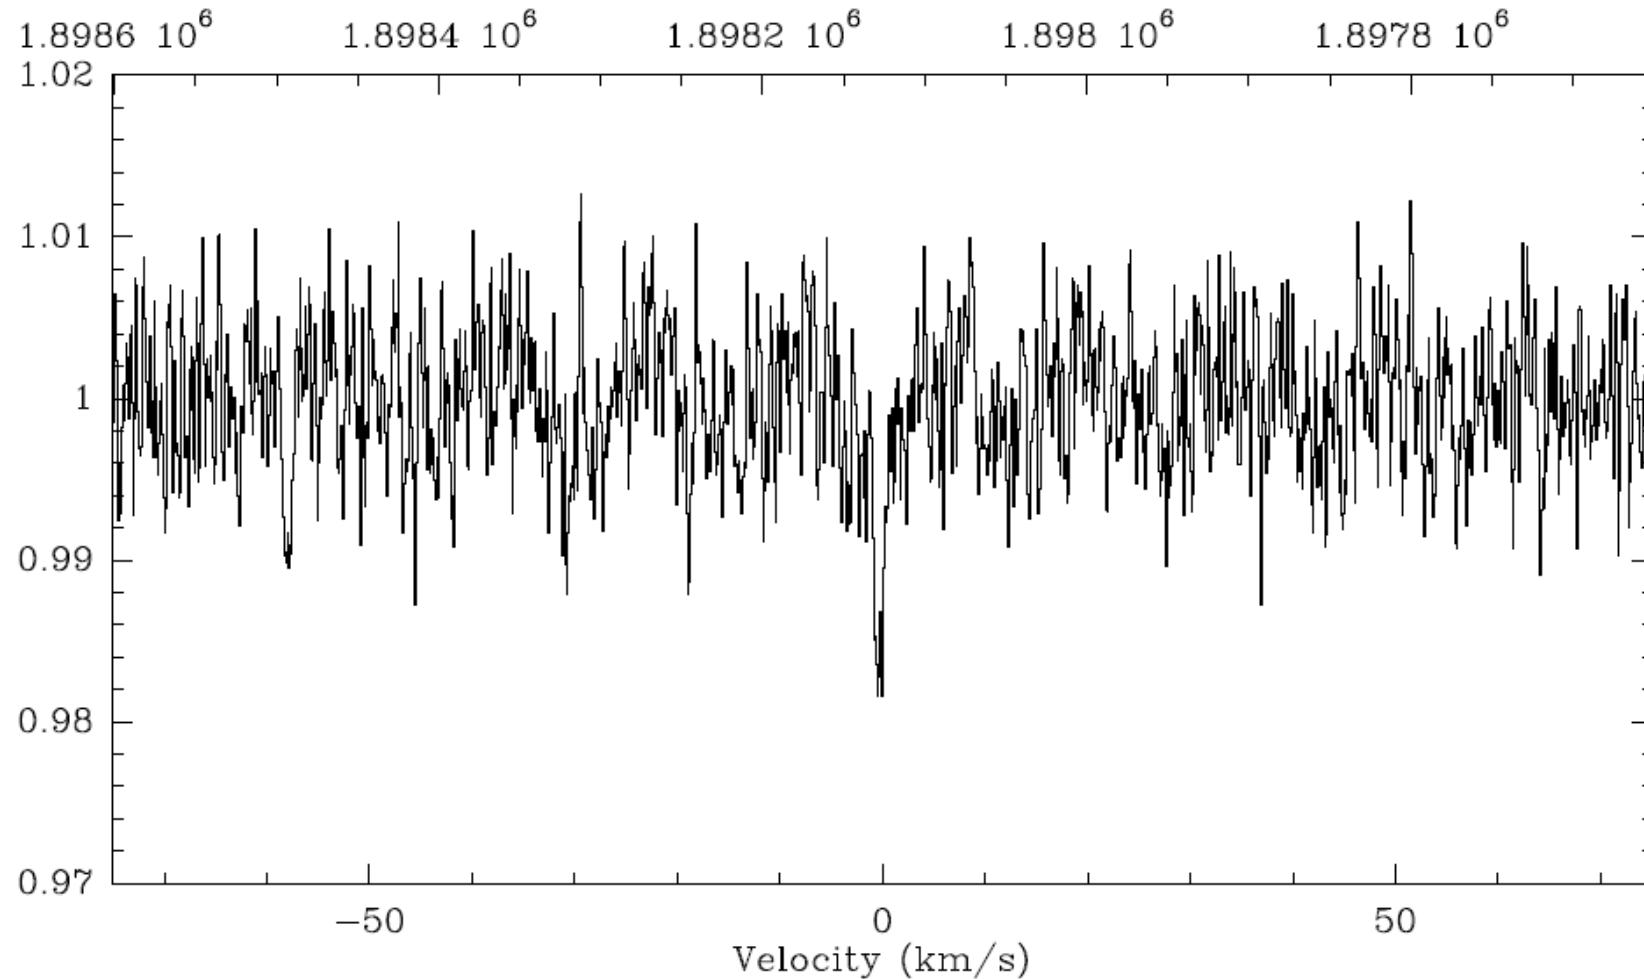

< 200 ppt

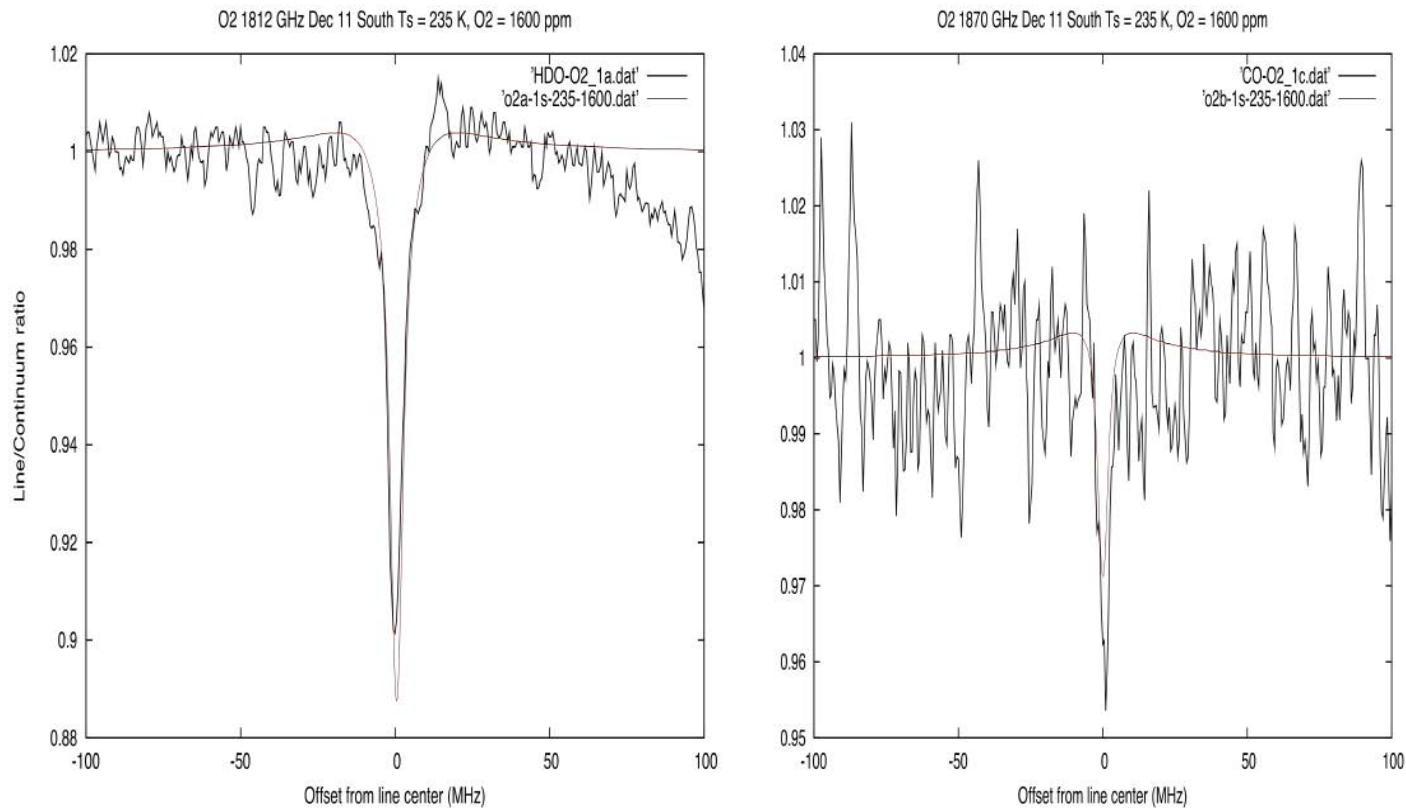

< 2 ppb

Fall 2011: detection of H₂O₂! Ls=10°

O₂ at 1812 GHz L_s=47°

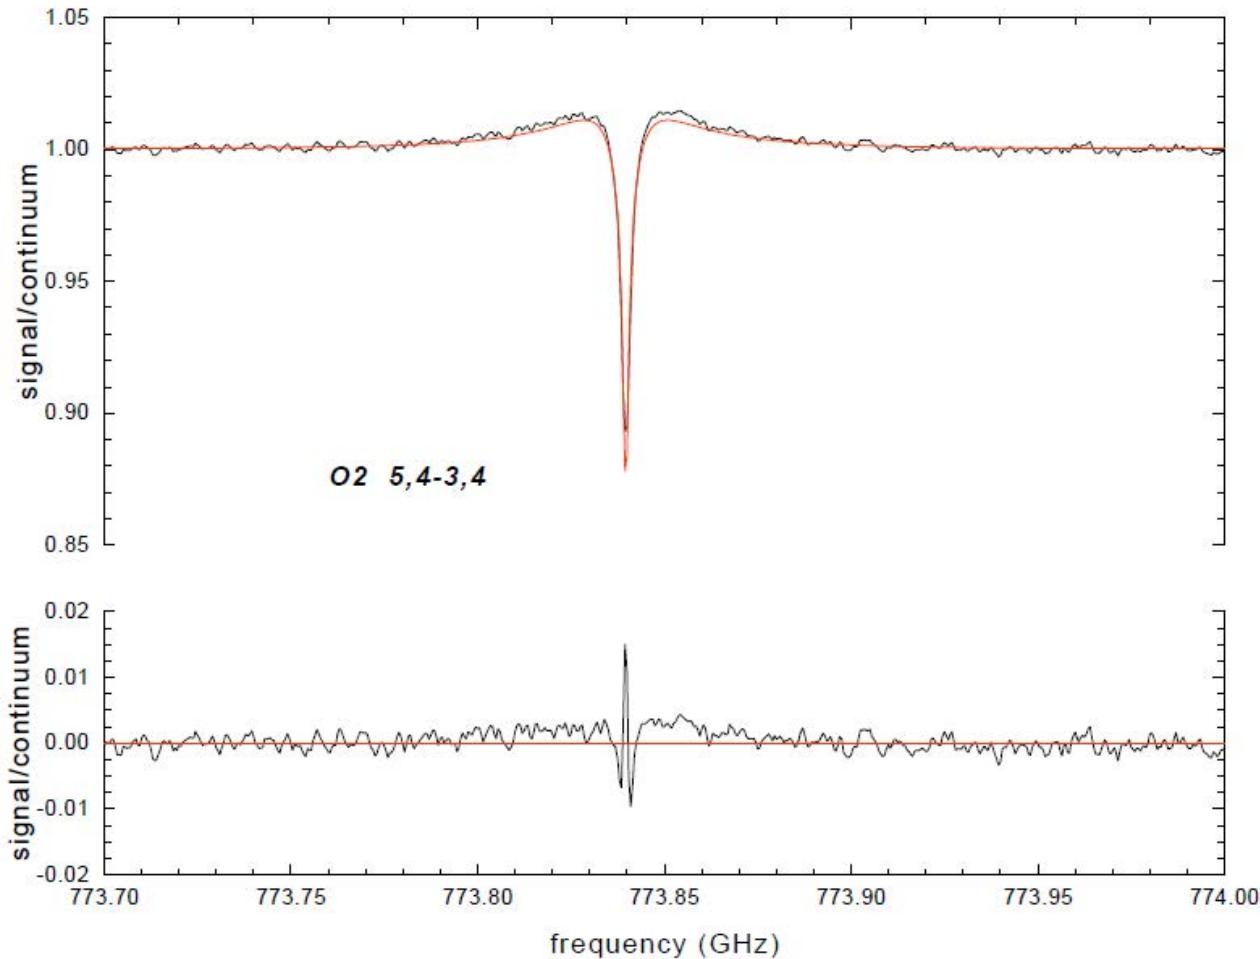

HIFI/Herschel, Dec 22, 2011, South – L_s = 47° - O₂ = 1600 ppm

T. Encrenaz et al.: no detectable spatiotemporal variation

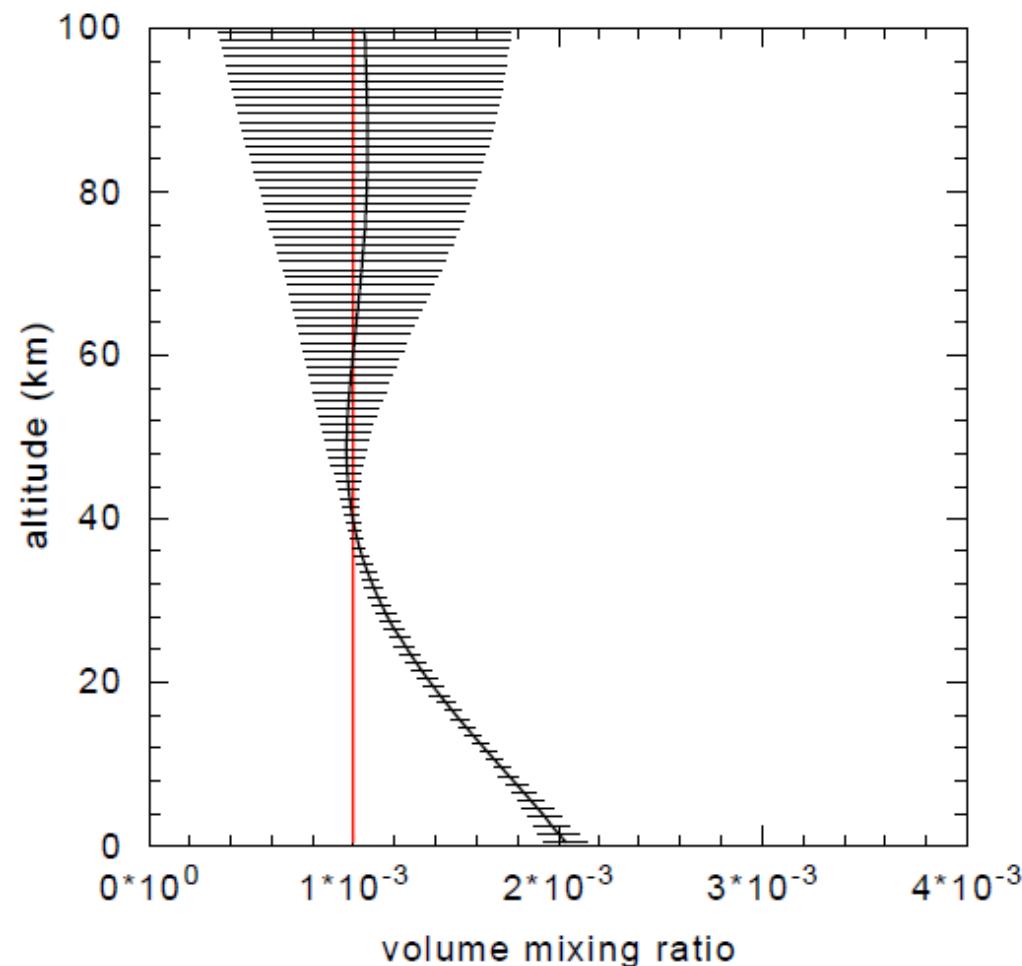

First submm detection of O₂

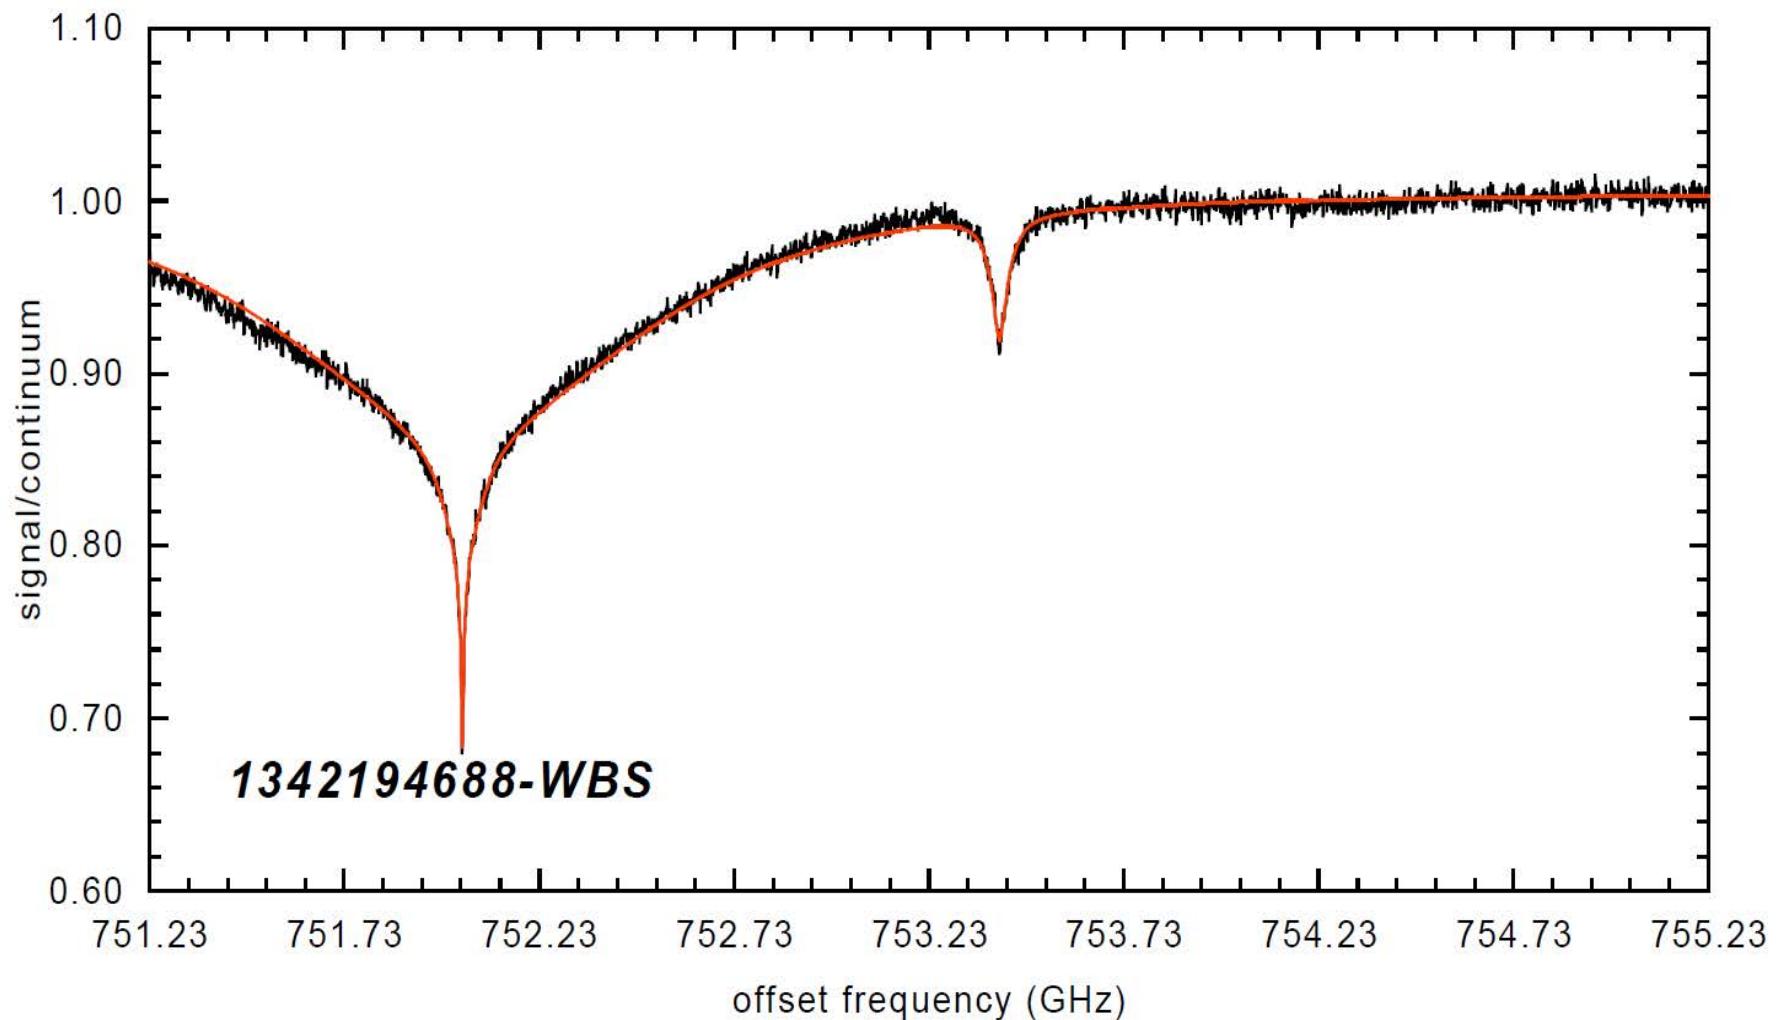

Fit of constant profile provides volume mixing ratio of 1400 ppm. However residual indicates that profile is not constant with altitude.

Hartogh et al. 2010b, A&A

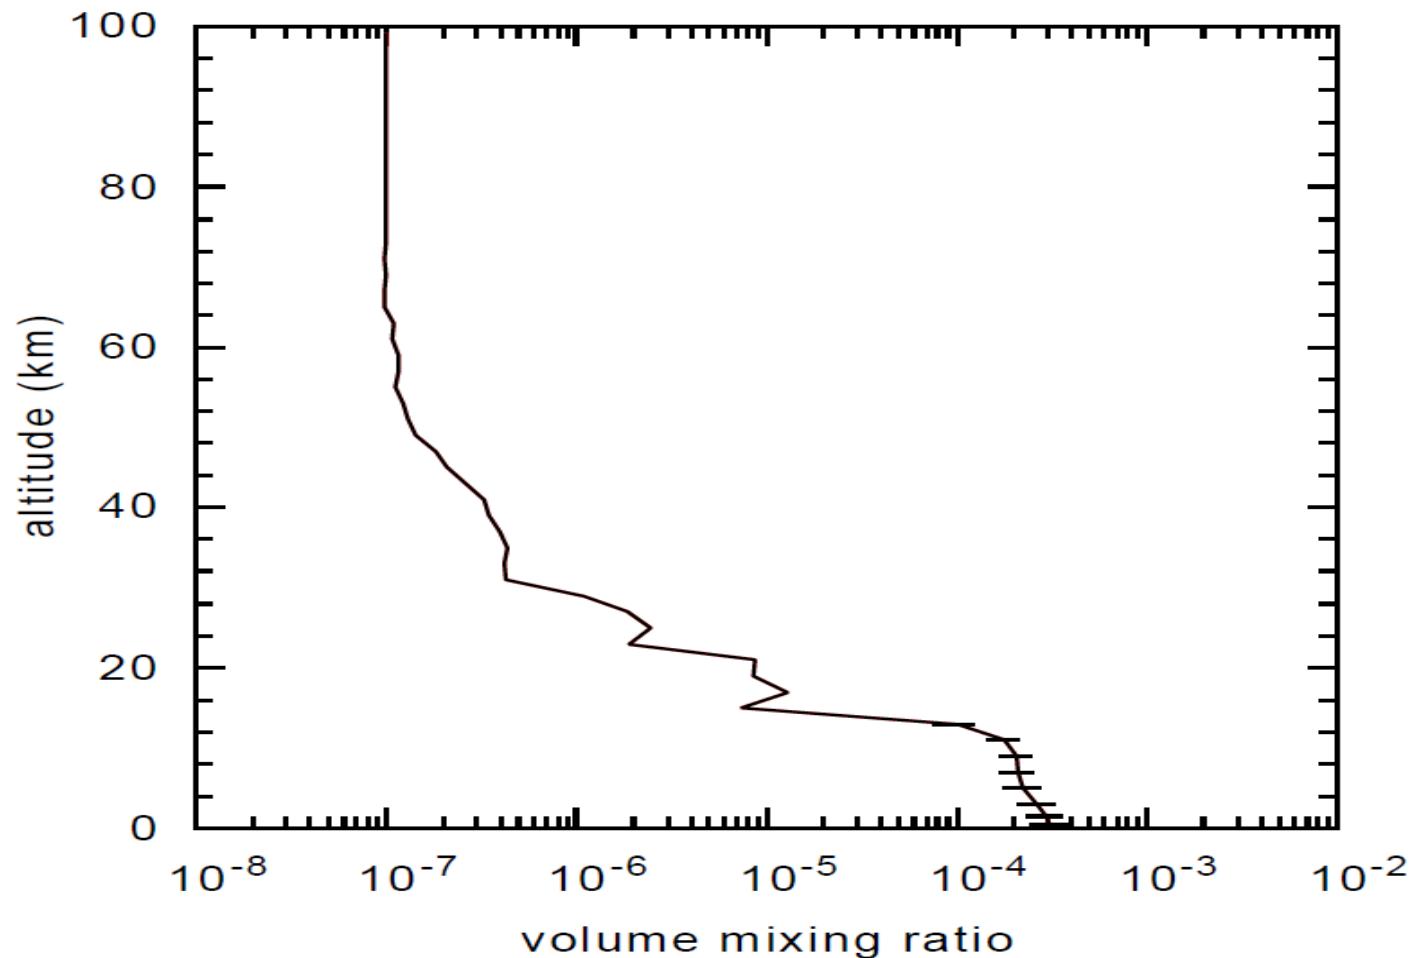

First results: vertical profile of O₂ on Mars, TBC

H_2O and HDO at $\text{Ls} = 78^\circ$

Vertical profile of water at Ls = 78°

Summary

- Herschel provided exciting solar system data (3 % of the total Herschel observing time)
- Numerous new discoveries:
 - new molecules (e.g. in Titan)
 - new atmospheres (e.g. Ceres, Ganymede, Callisto)
 - new water cloud (Enceladus water torus)
 - ocean like water in comets (e.g. 103P Hartley 2)
 - new views about planet formation (e.g. Uranus/Neptune)
 - new exciting questions (e.g. oxygen on Mars)
- More to come soon....
